A PREVALENCE STUDY OF MOSQUITOES IN LAGOS METROPOLIS

By

AJALA, ABIGAIL AYODELE

B.Sc. Zoology (Ife)

**A THESIS SUBMITTED IN PARTIAL FULFILMENT OF THE
REQUIREMENTS FOR THE AWARD OF THE DEGREE OF MASTER OF SCIENCE
(MEDICAL PARASITOLOGY), DEPARTMENT OF MEDICAL MICROBIOLOGY
AND PARASITOLOGY, FACULTY OF BASIC MEDICAL
SCIENCES,
OBAFEMI AWOLowo UNIVERSITY, ILE-IFE.**

2016

CERTIFICATION

I certify that this project was conducted by AJALA, ABIGAIL AYODELE (BMSP13/14/H/1951) under my supervision and approved by me in partial fulfillment of the requirements for the award of Master of Science (M.Sc.) degree in Medical Parasitology, Department of Medical Microbiology and Parasitology, Faculty of Basic Medical Sciences, ObafemiAwolowo University, Ile-Ife, Osun State, Nigeria.

DEDICATION

This project is dedicated to the Almighty God for his help, provision, direction, strength and for sparing my life so as to witness the completion of the study. It is also dedicated to the Ajala and Afolabi families plus the Love of my life, Orofin Zechariah Oluwabunmi .

OBAFEMI AWOLOWO UNIVERSITY

ACKNOWLEDGMENTS

Those that know their God shall do exploit. I thank the Almighty God, father of our Lord Jesus Christ, the gracious, the merciful and the provider, who, out of His infinite grace has made me witness the end of my M.Sc. programme.

I express my profound gratitude to my mentor, teacher, supervisor, Dr., T.A.(B.), Ogunniyi for his guidance, advice, financial support, constructive criticism and thorough supervision of this project. He is a father. May Almighty God continue to bless you sir (Amen).

My sincere appreciation goes to my parents Elder and Deaconess Moses Ajala, SSgt and Deaconess Afolabi for the love and support showed towards me during the course of study. I pray that God will make your dream about my success a reality and give you long life to reap the fruit of your labour. I also thank my brothers and their wives, Pastor and Mrs. Olufemi Ajala, Mr and Mrs. Olanrewaju Ajala, Mr Olabisi Afolabi, and my sisters Mrs. Folashade Oyedemi, Mrs. Victoria Kolade, Barrister Elizabeth Ajala, Miss Josephine Afolabi, and Miss Dorcas Afolabi for their support and encouragement, I am blessed to have you all. My heartfelt appreciation goes to Orofin Zechariah Oluwabunmi, a brother, friend, and lover, for always being there for me, I say “you are highly appreciated”. Your invaluable love, support and encouragements throughout the course of the study can never be measured, “I love you dearly”, you are wonderful. God bless you. I say a big thank you to the family of Orofin for their support, love and prayers. May the Almighty God bless you. To the Scholarship board of The First Baptist Church, 24a Broad street Lagos, I say a big thank you, may the Lord continue to move His church forward.

I will not forget my colleague, Mr. Olaosebikan Olawale you are wonderful, thank you for your cooperation. God will order our steps in Jesus name.

To Mr. OlaniranOlarinde, DrDonbraye and Dr. B.W. Odetoyin of the Department of Medical Microbiology and ParasitologyO.A.U Ile Ife, Dr. Amole and Mr.OjongbedeOlumuyiwa Louis of the Department of Medical Microbiology and Parasitology, Lagos State University Teaching Hospital, MrAwotile the Chief Laboratory Technologist of the Department of Zoology, O.A.U, Ile-Ife,I say thank you very much .

I would like to thank my friends, BalogunOpeoluwa, AfolabiAanuoluwapo,AkinremiOmotayo and AdegbenjoFunmilola for their love and support.

ABSTRACT

The study investigated the prevalent genera of mosquitoes in Lagos metropolis based on the characteristic morphology of their larvae. It also determined the likely possible variations in prevalence of mosquito larvae in different localities of the study area, and likely seasonal variation in prevalence.

Mosquito larvae were collected partly during the rainy season (August and September, 2015) and partly in the dry season, (November and December, 2015) from seventeen (17) Local Government Areas (LGAs) of Lagos within the metropolis (core Lagos). These are Ojo, Amuwo Odofin, Apapa, Ajeromi/Ifelodun, Mainland, Surulere, Lagos Island, Mushin, Oshodi, Isolo, Shomolu, Kosofe, Alimosho, Ikeja, Agege, Eti-osa and Ifaki Ijaye. Five potential breeding sites in the LGAs, namely gutters, discarded tyres, discarded containers, household containers, and abandoned concrete electric poles were identified in both seasons. The collection of mosquito larvae was done using dipper and Pasteur pipette. Mosquito larvae were identified at the Department of Medical Microbiology and Parasitology, Lagos State University Teaching Hospital (LASUTH). Mosquito larvae collected were poured into Petri dish for counting. The larvae were then poured into glass bottle and heated for five minutes to kill them. The larvae were further dehydrated in increasing concentration of ethanol (20%, 40%, 60%, 80% and absolute) for twenty minutes per concentration. They were cleared in xylene, and mounted in Distrene Plasticer Xylene (D.P.X.) on a dry microscope slide, covered with cover slip. Thereafter, the slides were viewed under microscope with $\times 4$ objective lens. Data collected were analyzed using One way analysis of variance (ANOVA), Repeated analysis of variance and Student t-test. Alpha level was set at $P < 0.05$ of significance.

Out of a total of 340 breeding sites investigated, only 125 of them contained mosquito larvae. A total of 2380 mosquito larvae belonging to three genera were collected and identified. These were *Aedes* 1502(63.1%), *Culex* 869(36.5%) and *Anopheles* 9(0.4%). In both raining and dry seasons, *Aedes* were predominant in discarded tyres. *Culex* were predominant in both seasons in the gutters. In discarded containers, *Aedes* were predominant in both seasons. In abandoned concrete electric poles, *Aedes* were predominant in the rainy season while no mosquito larvae was observed in the poles in the dry season. In household containers in the rainy season, *Culex* were the most abundant but in the dry season *Aedes* was. Few *Anopheles* were observed in the gutters and discarded tyres. There was no statistically significant difference ($P>0.05$) in the larvae genera collected in different breeding sites in the raining and dry seasons. There was also no statistically significant difference ($P>0.05$) in the larvae distribution in the LGAs in the rainy and dry seasons.

The study concluded that *Aedes* were the predominant mosquitoes in the study area followed by *Culex*. In view of the fact that a few number of *Anopheles* were encountered, there seems to be no justification for the high cases of malaria that is usually insinuated. Therefore diseases that may be emerging are those caused by the pathogens carried by the predominant two genera of mosquitoes.

CHAPTER ONE

INTRODUCTION

Mosquito belongs to the Phylum Arthropoda; Class Insecta; Order Diptera (True flies), sub order Nematocera, family Culicidae. There are two important subfamilies which are the Anophelinae and Culicinae (White, 2002). The Anophelinae subfamily consist of three genera which are *Anopheles*, *Bironella* and *Chagasia*. The subfamily Culicinae is the largest subfamily of mosquitoes. Species belonging to this subfamily are referred to as 'culicines'. The culicines consist of 4 tribes: Sabethine having only one genus *Sabethes*, Aedini tribe having 4 genera which are; *Aedes* (980 species), *Haemagogus*, *Eretmapodite* and *Psorophora*. Culicini tribe with only one genus *Culex* (800 species) and finally Mansoniini tribe having only one genus *Mansonia* (78 known species) (Gordon and Lavoipierre, 1962; Maurice and Robert, 1969). There are more than 4500 species of mosquitoes distributed throughout the world and groupable into 34 genera; but mostly belonging to *Aedes*, *Anopheles* and *Culex* (Ghosh *et al.*, 2013).

Mosquitoes are found throughout the world except in places that are permanently frozen such as Antarctica (Reiter, 2001). However it is only in the tropics that they assume medically important roles. *Anopheles*, *Aedes* and *Culex* are distributed world wide, *Chagasia* is restricted to South America, *Bironella* has a geographical distribution of Australoasia. *Sabethes* is neo-tropical in distribution, found only in South and Central America. *Haemagogus* is neo-tropical in distribution, found in South and North America. *Eretmapodite* is restricted to Africa. *Psorophora* is found in Southern part of U.S.A and Central and South America. *Mansonia*

is found in several parts of the world but assume important role in health in South East Asia (Maurice and Robert 1969).

Mosquitoes require water bodies for breeding (WHO,1982)and undergo holometabolous (complete)type of metamorphosis, which has four stages of development which are the egg, larva, pupa, and adult (Cranston *et al.*,1987).Mosquito breeding sites are often created by human or animal activities wherein larvae are found in small depressions including foot or hoof prints, edges of boreholes and burrow pits, road side puddles formed by tyre tracks, irrigation ditches and other artificial bodies of water (Gimniget *al.*, 2001). The increase in environmental modification as a result of urbanization is usually being accompanied by creation of more breeding sites for mosquitoes which, most often, lead to an increase in the incidence of mosquito borne diseases (Amusanet *al.*,2003).

According to the World Health Organization (W.H.O), mosquitoes are ‘Public Enemy No.1’ (WHO, 1996). Mosquitoes are,however,the most important single group of insects which cause millions of death every year by transmitting pathogens which are agents of various diseases such as dengue fever, Chikungunya virus, Yellow Fever, Lymphatic Filariasis, Japanese B-encephalitis, Malaria (Becker *et al.*,2010; Barik *et.al.*, 2012), Zika virus (WHO, 2016).

Malaria is a major global public health problem but has been considered predominantly a rural disease in Africa, primarily because suitable *Anopheles* mosquito breeding sites are few in highly populated urban areas (Keating *et al.*,2004).Malaria still kills more people than HIV/AIDS or any other killer disease and it is endemic throughout Nigeria, accounting for 25% of infant mortality and 30% of childhood mortality (FMOH, 2005).Malaria is caused by the protozoan *Plasmodium*, which is transferred to humans through bites ofinfected female

Anopheles mosquitoes (Choumet, 2012). Nigeria has achieved so much in its malaria control efforts in the past few years and has moved down from hyper endemic i.e a situation where about 50% of the population at any time will test positive, when they have fever, to a meso endemic nature, which is the level that you test about 100 people and less than 25 are positive especially in most urban areas (Ntadom,2015).

In urban areas, water pollution is believed to be a major factor that generally reduces the development of anopheline larvae. There is evidence to the fact that *Anopheles* mosquito breeding sites decrease from rural to urban areas and transmission intensity is on the average eight times greater in African rural areas than urban centres (Hayet *al.*, 2000; Robertet *al.*, 2003). Even so, malaria transmission is reported to still occur in most urban cities and pregnant women and children under 5 years are said to be at risk (Awolola *et al.*, 2007).

Mosquitoes can thrive in a variety of habitats with fresh water, brackish water, or any water (clear, turbid or polluted) except in marine habitats with high-salt concentration (Rueda, 2008). Mosquito breeding places in and around houses can be divided into two main types; breeding sites with clean water mainly rain-filled receptacles in humid tropical areas which are suitable breeding sites for some *Aedes* species. These habitats are favored by *Aedes aegypti*, *Aedes albopictus* and *Aedes vittatus* which can act as a vector of dengue virus and also a dengue vector referred to as the Asian tiger mosquito by Americans. These species also breed in containers that are used to store water for drinking or washing. The second breeding sites are polluted water mainly gutters and discarded tyres which are suitable breeding sites for *Culex* and *Aedes* species respectively (Rajeshet *al.*, 2014).

Urbanization is one of the factors that increase the number of habitats suitable for *Aedes* mosquitoes, especially *Ae. aegypti* (WHO, 2008). While *Ae. aegypti* is commonly found inside

houses, *Ae.albopictus* more common in outside areas, in open spaces with shaded vegetation and suitable breeding sites such as car tyres and garbage dumps (WHO, 1986). Breeding places in the city arise from neglected features of the construction sites, stagnant drain water collections, tanks, coolers and receptacles of rain water collections.

1.1 Justification for research work
